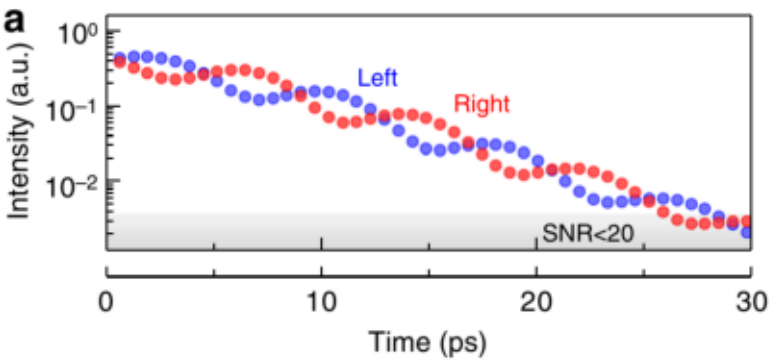
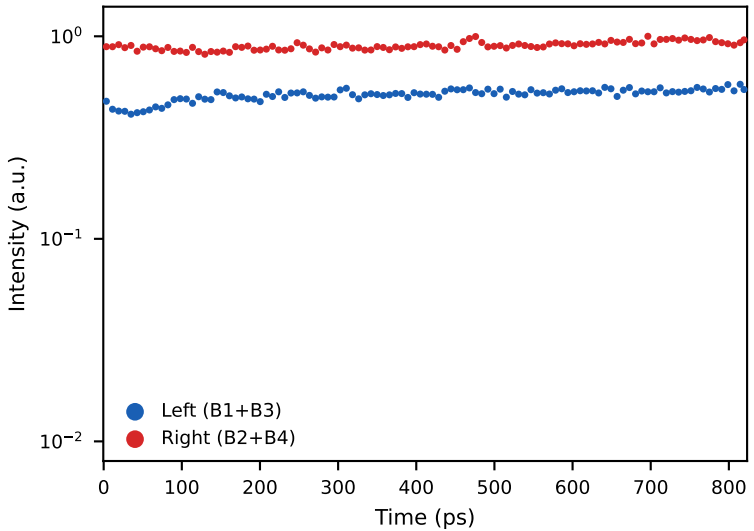
Adiyatullin et al. 2017 (Nat. Commun. 8:1329), Fig. 2(a)



This work: 26-08-04 HBT supplement, 72000 frames, CFD5



Left: original Fig. 2(a) of Adiyatullin et al. 2017 (Nat. Commun. 8:1329)— accumulated emission intensity of the left (blue) and right (red) mesa on a logarithmic scale, showing anti-phase population oscillations; the gray band marks the low-confidence SNR<20 region. Right: this work — replication on the 72000-frame supplement batch (photon-event source, rebin 8≈ 7.9 ps/bin, peak-normalized; Poisson-FDR + S/N-optimal band windows, App. B.1). Each condensate is recorded simultaneously by both HBT arms; the plotted intensity sums its two arm bands (Left = B1+B3, Right = B2+B4). Per-frame time zero by CFD50; measured background subtracted. Outcome: no anti-phase oscillation — 95% upper limit on a phase-locked sinusoidal z amplitude: median 0.009, worst 0.016 over 3-200 ps periods; cross-arm detrended fluctuations uncorrelated (r = 0.09-0.12, p = 0.07–0.09); the early left-side dip is an overdamped monotonic recovery, not an oscillation.
